Dr. A. Kotzig
Department of Mathematics
University of Bratislava
Bratislava, Czechoslovakia

Dear Dr. Kotzig:

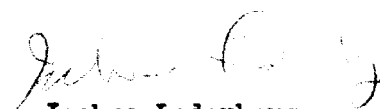

The volume "Theory of Graphs and its Applications" has just come to my attention and I was most interested to see your contribution in it. I would be most grateful for an exchange of publications (and especially for any English versions or abstracts you may have).

I have no pretensions as a mathematician, but you may be interested in some results of our computations of trivalent graphs in connection with applications to chemistry. These are being consolidated into a more coherent report.

My main aim is to challenge some graph specialists to make a more orderly analysis of this set of graphs. I am especially annoyed with the non-polygonal ones, which become rather intractable (though still manageable even in this clumsy system) at $n = 14$.

Is there a convex trivalent polyhedron of which just one edge may not be included in any Hamilton circuit? (The pentagonal prism is an example which has a pair of edges that are mutually exclusive, as exploited by Tutte for his famous example.

Sincerely yours,

Joshua Lederberg
Professor of Genetics
